

Lower Bounds for Enumerative Counts of Positive-Genus Real Curves, Appendix

Jingchen Niu* and Aleksey Zinger†

November 6, 2015

Positive-genus real GW-invariants of real orientable symplectic manifolds of odd “complex” dimensions are constructed in [2]. The genus 1 real GW-invariants of sufficiently positive targets of “complex” dimension 3, such as \mathbb{P}^3 , have no contribution from genus 0 curves and thus directly provide lower bounds for the number of real genus 1 irreducible curves in such manifolds; see [3, Theorem 1.5] for a precise statement. The real invariants of higher genus do have such contributions; they are determined by [9, (1.6)]. This relation is lower-triangular with respect to the genus and thus can be used to determine invariant signed counts of real genus g curves from the real GW-invariants of genus g and lower.

The real GW-invariants of \mathbb{P}^{2m-1} can be computed using the virtual localization theorem of [6] and the equivariant localization data of [3, Theorem 4.6]. They are used to compute the genus g degree d real GW-invariant of \mathbb{P}^3 with d pairs of conjugate point constraints with $d \leq 4$ in [3, Section 4.3] and [9, Section 6]. The accompanying hand-drawn graphs and *Mathematica* printouts, which are the work of the first named author, compute these invariants for

- $d=5, 7$ and $g=0, 2, 4$, and
- $d=6, 8$ and $g=1, 3, 5$.

By [3, Theorem 1.6], the genus g degree d real GW-invariant of \mathbb{P}^3 with $d-g \in 2\mathbb{Z}$ vanish. The $g=0$ numbers obtained in the accompanying notes agree with [1, Table 1]. The $(g, d)=(1, 6)$ number is also obtained in [4] through a less systematic localization computation.

The accompanying notes apply the equivariant localization theorem of [6] with the standard $(\mathbb{C}^*)^2$ -action on \mathbb{P}^3 with its standard conjugation τ_4 . The relevant localization data in the present setting is described in detail in [9, Section 6.1], specializing from the more general setting of [3, Theorem 4.6]. We denote the weights of this action by $\alpha_1 = -\alpha_2$ and $\alpha_3 = -\alpha_4$; they correspond to the fixed points P_1, P_2, P_3, P_4 with $P_1 = \tau_4(P_2)$ and $P_3 = \tau_4(P_4)$. For $i \in \mathbb{Z}$, let

$$\langle i \rangle = \begin{cases} 1, & \text{if } i \notin 2\mathbb{Z}; \\ 3, & \text{if } i \in 2\mathbb{Z}. \end{cases}$$

*Partially supported by DMS Grants 0846978 and 1500875

†Partially supported by DMS Grant 1500875 and MPIM

The genus g degree d real GW-invariant of \mathbb{P}^3 with d pairs of conjugate point constraints then equals

$$\text{GW}_{g,d}^{\mathbb{P}^3,\tau_4}(\underbrace{H^3, \dots, H^3}_d) = \int_{[\overline{\mathcal{M}}_{g,d}(\mathbb{P}^3,d)\tau_4]^{\text{vir}}} \prod_{i=1}^d \left(\text{ev}_i^* \prod_{j \neq (i)} (\mathbf{x} - \alpha_j) \right) \quad (\star)$$

where \mathbf{x} is the equivariant hyperplane class.

In the non-equivariant reduction, $\alpha_k = 0$ and (\star) becomes integration of pullbacks of the Poincare dual of the point in \mathbb{P}^3 . The use of Pandharipande's trick of twisting by the equivariant weights reduces the number of contributing torus-fixed loci (the restrictions of the integrand to other loci vanish). This trick works spectacularly in reducing the proof of the Aspinwall-Morrison formula to computing the contribution of the simplest possible fixed locus; see [7, Lemma 27.5.3]. In our case, it leaves only the fixed loci consisting of morphisms passing through all 4 torus-fixed points and severely restricts the possible distributions of the d conjugate pairs of marked points.

For $d = 5, 6, 7, 8$, the hand-drawn diagrams show every type of graph possibly contributing to (\star) . The $d = 5$ graphs show half of the possible assignments of the vertex labels indicating the associated fixed point in \mathbb{P}^3 ; the other half is obtained by interchanging the labels 3 and 4. The $d = 6, 7, 8$ graphs show only a quarter of these assignments; the remainder are obtained by swapping the role of the pair (1, 2) with that of (3, 4) and/or by interchanging the labels 3 and 4. In all cases, the sums are taken over all admissible distributions of the degree between the edges, of the genus between the vertices, and of the marked points between the vertices. The last distribution is subject to the condition that the odd-numbered marked points are mapped to the vertices labeled 1 and 2 and the even-numbered marked points are mapped to the vertices labeled 3 and 4. The number above the curly bracket (or aside the circled vertices if $d = 7, 8$) of each graph indicates the number of marked points to be distributed between the associated vertices. The graphs that cancel in pairs according to [3, Corollary 4.8] are not shown in these pictures. The set of all relevant graphs for each degree is followed by a computation, via [9, (1.7)], of the enumerative invariants in the three relevant genera from the corresponding numbers obtained in the associated *Mathematica* printout.

In the *Mathematica* computations, the weights α_1 and α_3 are denoted by x and y . All four weights, along with one set of copies, are put into the vector called a . The functions EC and ER encode the complex and real edge contributions given by (6.9) and (6.10), respectively, in [9]. The functions Z and $L0$ compute the integrals of ψ -classes over the Deligne-Mumford moduli spaces $\overline{\mathcal{M}}_{g,m}$ of genus g k -marked complex curves with $g = 0, 1, 2$, respectively. The functions $L1$ and $L3$ compute the integrals of the forms

$$\int_{\overline{\mathcal{M}}_{2,k}} c_1(\mathbb{E}) \psi_1^{b_1} \dots \psi_k^{b_k} \quad \text{and} \quad \int_{\overline{\mathcal{M}}_{2,k}} c_1(\mathbb{E})^3 \psi_1^{b_1} \dots \psi_k^{b_k},$$

respectively, where $\mathbb{E} \rightarrow \overline{\mathcal{M}}_{g,k}$ is the Hodge vector bundle of holomorphic differentials. The remaining relevant Hodge integrals are determined from

$$\begin{aligned} c_2(\mathbb{E}) &= \frac{1}{2} c_1(\mathbb{E})^2, & \int_{\overline{\mathcal{M}}_{0,k}} \psi_1^{b_1} \dots \psi_k^{b_k} &= \binom{k-3}{b_1, \dots, b_k}, \\ \int_{\overline{\mathcal{M}}_{1,k}} c_1(\mathbb{E}) \psi_1^{b_1} \dots \psi_k^{b_k} &= \frac{1}{24} \binom{k-1}{b_1, \dots, b_k}, & \int_{\overline{\mathcal{M}}_{2,k}} c_1(\mathbb{E})^2 \psi_1^{b_1} \dots \psi_k^{b_k} &= \frac{7}{2880} \binom{k+1}{b_1, \dots, b_k}; \end{aligned}$$

see [8, Section 5] for the first identity and [5, Section 1.3] for the other three. The function V encodes the vertex contributions given by (6.6)-(6.8) in [3].

The set of graphs for each degree is followed by a *Mathematica* printout computing the contributions of all graphs in the set. All four of these printouts begin with the above functions. They are then applied to the graphs in the set under consideration. The contribution of each graph in the *Mathematica* printout is labeled in the same way as the associated graph.
