

KHOVANOV HOMOLOGY

CUBE OF RESOLUTIONS

Let D_K be a tangle diagram. Assign to each crossing of D_K an integer $\{1, \dots, n\}$. $\{0, 1\}^n$ forms the vertices of a hypercube with edges $\alpha \xrightarrow{k} \beta$ where $\alpha_j = \beta_j$ for $j \neq k$ and $\alpha_k = 0, \beta_k = 1$. For each $\alpha \in \{0, 1\}^n$, associate the smoothing D_α of D_K where each crossing j is α_j -smoothed. If K is a link then, D_α is a disjoint union of circles in the plane.

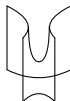

0-smoothing: $\diagdown \rightarrow \smile$

1-smoothing: $\diagdown \rightarrow \smile$ with a vertical line through the crossing

For each edge $\alpha \xrightarrow{k} \beta$, associate the cobordism of smoothings $D_{\alpha,\beta}$ which outside a neighborhood of the crossing change $N(k) \times I$ is the identity cobordism

$$(D_\alpha - N(k)) \times I = (D_\beta - N(k)) \times I$$

and within $N(k) \times I$ is a saddle cobordism. If K is a link then, $D_{\alpha,\beta}$ is a disjoint union of cylinders and one (possibly upside-down) pair of pants.

Saddle cobordism: 

For each $\alpha \in \{0, 1\}^n$ we can associate $r_\alpha = \sum_{j=1}^n \alpha_j$ and for each edge $\alpha \xrightarrow{k} \beta$ associate $r_{\alpha,\beta} = \sum_{j=1}^{k-1} \alpha_j = \sum_{j=1}^{k-1} \beta_j$.

KHOVANOV BRACKET

Define $[D_K] = \{[D_K]^i, d^i\}$ by

$$[D_K]^i = \bigoplus_{r_\alpha=i} D_\alpha$$

and $d^i : [D_K]^i \rightarrow [D_K]^{i+1}$ is the matrix of cobordisms

$$d_{\alpha,\beta}^i = \begin{cases} (-1)^{r_{\alpha,\beta}} D_{\alpha,\beta} & \alpha \xrightarrow{i} \beta \\ 0 & \text{otherwise} \end{cases}$$

Let $\begin{array}{ccc} \alpha & \rightarrow & \beta \\ \downarrow & & \downarrow \\ \gamma & \rightarrow & \delta \end{array}$ be a face of the hypercube. Then $D_{\beta,\delta}D_{\alpha,\beta} = D_{\gamma,\delta}D_{\alpha,\gamma}$ since these composite cobordisms are homeomorphic. Also

$$d^2 = \sum_{\begin{array}{ccc} \alpha & \rightarrow & \beta \\ \downarrow & & \downarrow \\ \gamma & \rightarrow & \delta \end{array}} (-1)^{r_{\alpha,\beta}}(-1)^{r_{\beta,\delta}}D_{\beta,\delta}D_{\alpha,\beta} + (-1)^{r_{\alpha,\gamma}}(-1)^{r_{\gamma,\delta}}D_{\gamma,\delta}D_{\alpha,\gamma}$$

But if $\alpha \xrightarrow{j} \beta$, $\gamma \xrightarrow{j} \delta$, $\beta \xrightarrow{k} \delta$ and $\alpha \xrightarrow{k} \gamma$, then if $j < k$ then $r_{\alpha,\beta} = r_{\gamma,\delta}$ and $r_{\beta,\delta} = r_{\alpha,\gamma} + 1$ and if $j > k$ then $r_{\alpha,\beta} = r_{\gamma,\delta} - 1$ and $r_{\beta,\delta} = r_{\alpha,\gamma}$. Thus,

$$d^2 = 0$$

We need to construct the category where $[D_K]$ lives. Given finite $A, B \subset (0, 1)$, let $Cob(A, B)$ be the category with objects 1-manifolds D in $(0, 1) \times [0, 1]$ with endpoints $\partial D = A \times \{0\} \cup B \times \{1\}$ and with morphisms, cobordisms $D_\alpha \rightarrow D_\beta$. These cobordisms are 2-manifolds $D_{\alpha,\beta}$ with corners embedded in $(0, 1) \times [0, 1] \times [0, 1]$ with boundary

$$\partial D_{\alpha,\beta} = \underbrace{A \times \{0\} \times [0, 1] \cup B \times \{1\} \times [0, 1]}_{y\text{-boundary}} \cup \underbrace{D_\alpha \times \{0\} \cup D_\beta \times \{1\}}_{z\text{-boundary}}$$

Cobordisms are considered up to boundary preserving ambient isotopies. Composition in $Cob(A, B)$, called vertical composition, is given by gluing along the z -boundary. There is a functor called horizontal composition $Cob(A, B) \times Cob(B, C) \rightarrow Cob(A, C)$ given by gluing along the y -boundary. There is another functor called the monoidal product $Cob(A, B) \times Cob(A', B') \rightarrow Cob(A \sqcup A', B \sqcup B')$ given by disjoint union, thought of as gluing along the (non-existent) x -boundary. This is the structure of a monoidal 2-category, Cob .

We can extend $Cob(A, B)$ by taking the preadditive closure $\overline{Cob(A, B)}$. Include all \mathbb{Z} -linear combinations of cobordisms $D_\alpha \rightarrow D_\beta$, and extend vertical composition linearly. Horizontal composition and monoidal product extend to \overline{Cob} linearly.

Next take the additive closure $\overline{\overline{Cob(A, B)}}$; include direct sums of objects $\oplus_\alpha D_\alpha$ and a 0 object with matrices of (linear combinations of) cobordisms between them and do vertical composition like matrix multiplication. Horizontal composition and monoidal product extend to $\overline{\overline{Cob}^*}$ by acting like tensor products.

Finally, let $Kob(A, B)$ be the category of cochain complexes in $\overline{\overline{Cob(A, B)}}$. Vertical composition in $Kob(A, B)$ is composition of chain maps. Horizontal composition and monoidal product extend to Kob by acting like tensor product of complexes. If D_K has source and target endpoints A, B , then $[D_K]$ is an object in $Kob(A, B)$.

LOCALITY AND SKEIN RELATION

Theorem. *The Khovanov bracket has the following properties:*

- (1) If D_K is the composition of two tangle diagrams D_0, D_1 then $[D_K]$ is the horizontal composition $[D_0] \otimes [D_1]$
- (2) If $D_K = D_0 \sqcup D_1$ then $[D_K]$ is the monoidal product $[D_0] \sqcup [D_1]$.

- (3) If tangle diagram D_K has 0,1-resolutions D_0, D_1 at some crossing j , then $[D_K]$ is the cone of the chain map $[D_0] \rightarrow [D_1]$ induced by the cobordism which is a saddle in the neighborhood of j .

The first two properties comprise locality of the Khovanov bracket and the third property is the skein relation.

Proof. Choose an ordering of the crossings in D_K so that crossings in D_0 are first. Then, a smoothing D_α is a composition of smoothings $D_{\alpha^0} \otimes D_{\alpha^1}$ where $(\alpha_1, \dots, \alpha_n) = (\alpha_1^0, \dots, \alpha_j^0, \alpha_1^1, \dots, \alpha_{n-j}^1)$. We have that $r_\alpha = r_{\alpha^0} + r_{\alpha^1}$ so that

$$[D_K]^i = \bigoplus_{r_\alpha=i} D_\alpha = \bigoplus_{r_{\alpha^0}+r_{\alpha^1}=i} D_{\alpha^0} \otimes D_{\alpha^1} = ([D_0] \otimes [D_1])^i$$

Given an edge $\alpha \rightarrow \beta$, either there is an edge $\alpha^0 \rightarrow \beta^0$ and $\alpha^1 = \beta^1$ or $\alpha^0 = \beta^0$ and there is an edge $\alpha^1 \rightarrow \beta^1$. Writing id_α for identity cobordisms, we have that $D_{\alpha,\beta} = D_{\alpha^0,\beta^0} \otimes id_{\alpha^1}$ in the first case or $D_{\alpha,\beta} = id_{\alpha^0} \otimes D_{\alpha^1,\beta^1}$ in the second case. The matrix d_ϵ is $(-1)^{r_{\alpha^\epsilon,\beta^\epsilon}} D_{\alpha^\epsilon,\beta^\epsilon}$ if there is an edge $\alpha^\epsilon \rightarrow \beta^\epsilon$ and 0 otherwise. The matrix id_ϵ is id_{α^ϵ} if $\alpha^\epsilon = \beta^\epsilon$ and 0 otherwise. Thus,

$$\begin{aligned} d_0 \otimes id_1 + (-1)^{r_{\alpha^0}} id_0 \otimes d_1 &= \\ \begin{cases} (-1)^{r_{\alpha^0,\beta^0}} D_{\alpha^0,\beta^0} \otimes id_{\alpha^1} \pm 0 \otimes 0, & \alpha_0 \rightarrow \beta_0, \alpha_1 = \beta_1 \\ 0 \otimes 0 + (-1)^{r_{\alpha^0}} id_{\alpha^0} \otimes (-1)^{r_{\alpha^1,\beta^1}} D_{\alpha^1,\beta^1} & \alpha_0 = \beta_0, \alpha_1 \rightarrow \beta_1 \\ 0 & \text{otherwise} \end{cases} \\ &= \begin{cases} (-1)^{r_{\alpha,\beta}} D_{\alpha,\beta} & \alpha \rightarrow \beta \\ 0 & \text{otherwise} \end{cases} = d \end{aligned}$$

So, $[D_K] = [D_0] \otimes [D_1]$. The proof for monoidal product is entirely analagous.

In the case $D_K = \smile$, the skein relation is easy to verify.

$$\begin{aligned} C \left(\begin{array}{c} \smile \\ \uparrow \\ \smile \end{array} \right) &= C \left(\begin{array}{cccc} 0 & \leftarrow & \smile & \leftarrow & 0 \\ & & \uparrow & & D_{0,1} \\ 0 & \leftarrow & \smile & \leftarrow & 0 \end{array} \right) \\ &= 0 \leftarrow 0 \oplus \smile \leftarrow \left(\begin{array}{cc} 0 & 0 \\ D_{0,1} & 0 \end{array} \right) \smile \oplus 0 \leftarrow 0 \\ &= 0 \leftarrow \smile \leftarrow \left(\begin{array}{c} D_{0,1} \\ \smile \end{array} \right) \leftarrow 0 = [\smile] \end{aligned}$$

The general case then follows by locality and the properties of cones of tensor products. \square

GRADING

For $D_{\alpha,\beta}$ a cobordism in $Cob(A, B)$ let $deg(D_{\alpha,\beta}) = \chi(D_{\alpha,\beta}) - \frac{|A|+|B|}{2}$.

We can see that vertical and horizontal composition and monoidal product are degree additive. For vertical composition,

$$\begin{aligned} deg(D_{\beta,\gamma} D_{\alpha,\beta}) &= \chi(D_{\beta,\gamma} D_{\alpha,\beta}) - \frac{|A|+|B|}{2} \\ &= \chi(D_{\beta,\gamma}) + \chi(D_{\alpha,\beta}) - \chi(D_\beta) - \frac{|A|+|B|}{2} \\ &= \chi(D_{\beta,\gamma}) - \frac{|A|+|B|}{2} + \chi(D_{\alpha,\beta}) - \frac{|A|+|B|}{2} \end{aligned}$$

$$= \text{deg}(D_{\beta,\gamma}) + \text{deg}(D_{\alpha,\beta})$$

For horizontal composition,

$$\begin{aligned} \text{deg}(D_{\alpha,\beta} \otimes D_{\alpha',\beta'}) &= \chi(D_{\alpha,\beta} \otimes D_{\alpha',\beta'}) - \frac{|A| + |C|}{2} \\ &= \chi(D_{\alpha,\beta}) + \chi(D_{\alpha',\beta'}) - |B| - \frac{|A| + |C|}{2} \\ &= \chi(D_{\alpha,\beta}) - \frac{|A| + |B|}{2} + \chi(D_{\alpha',\beta'}) - \frac{|B| + |C|}{2} \\ &= \text{deg}(D_{\alpha,\beta}) + \text{deg}(D_{\alpha',\beta'}) \end{aligned}$$

For monoidal product,

$$\begin{aligned} \text{deg}(D_{\alpha,\beta} \sqcup D_{\alpha',\beta'}) &= \chi(D_{\alpha,\beta} \sqcup D_{\alpha',\beta'}) - \frac{|A \sqcup A'| + |B \sqcup B'|}{2} \\ &= \chi(D_{\alpha,\beta}) - \frac{|A| + |B|}{2} + \chi(D_{\alpha',\beta'}) - \frac{|A'| + |B'|}{2} \\ &= \text{deg}(D_{\alpha,\beta}) + \text{deg}(D_{\alpha',\beta'}) \end{aligned}$$

Thus, the set of morphisms $D_\alpha \rightarrow D_\beta$ in $\overline{Cob}(A, B)$ is a graded Abelian group $\bigoplus_i G_i$. Let $Cob_0(A, B)$ be the category with objects $D_\alpha\{a\}$, $a \in \frac{1}{2}\mathbb{Z}$ and morphisms

$$D_\alpha\{a\} \rightarrow D_\beta\{b\} \text{ equal to } \begin{cases} G_{b-a} & b - a \in \mathbb{Z} \\ \{0\} & \text{otherwise} \end{cases}. \text{ Also, let } Kob_0(A, B) \text{ be the category}$$

of chain complexes in the additive closure, $\overline{Cob}_0(A, B)$. Cob_0 and Kob_0 are monoidal 2-categories, by degree additivity.

Choose an orientation on D_K . Let n_-, n_+ be the number of negative, and positive crossings respectively. We define the graded Khovanov bracket

$$[D_K]^i = \bigoplus_{r_\alpha = n_- + i} D_\alpha\left\{\frac{n_+ - n_-}{2} - i\right\}$$

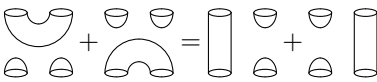

The coboundary still has the same definition. Identity cobordisms are disjoint unions of cylinders which have degree 0 and squares which also have degree 0, while saddle cobordisms have degree -1 . Indeed, the coboundary components are in $D_\alpha\left\{\frac{n_+ - n_-}{2} - i\right\} \rightarrow D_\beta\left\{\frac{n_+ - n_-}{2} - i - 1\right\} = G_{-1}$. Thus the coboundary is a morphism in $\overline{Cob}_0(A, B)$ and $[D_K]$ is an object in $Kob(A, B)$.

INVARIANCE

In order to get homotopy equivalences from Reidemeister moves we have to quotient by certain local relations.

Sphere relation:  = 0

Torus relation:  = 2

Four tube relation: 

These relations make sense in \overline{Cob} , so in Kob_0 . Modding out by local relations and homotopy equivalences we get $Kob_{0,l,h}$.

Theorem. *The isomorphism class of the graded Khovanov bracket $[D_K]$ in $Kob_{0,l,h}$ are invariants of the framed oriented tangle K represented by D_K as a blackboard diagram.*

Some preliminary work must proceed the proof.

Permutation of Crossings. Let σ be a permutation of $\{1, \dots, n\}$. Let σD_K be the tangle diagram D_K with crossings relabeled according to σ . Given $\alpha \in \{0, 1\}^n$, let $\sigma\alpha$ be given by $(\sigma\alpha)_i = \alpha_{\sigma(i)}$. Then, $r_{\sigma\alpha} = r_\alpha$ so, given $\alpha \xrightarrow{k} \beta$, and working in the ungraded case

$$[\sigma D_K]^i = \bigoplus_{r_\alpha=i} D_\alpha$$

$$(\sigma d)_{\alpha,\beta}^i = \begin{cases} (-1)^{r_{\sigma\alpha,\sigma\beta}} D_{\alpha,\beta} & \alpha \xrightarrow{i} \beta \\ 0 & \text{otherwise} \end{cases}$$

Let $R_\alpha = \{j : \alpha_j = 1\}$. The natural ordering on $\{1, \dots, n\}$ induces an ordering on R_α . σ induces a permutation σ_α on the ordering of R_α . Define $\uparrow \Sigma$ where $\uparrow \Sigma$ where $[D_K]$

Σ^i is a diagonal matrix with $\Sigma_{\alpha,\alpha}^i = \text{sign}(\sigma_\alpha) id_{D_\alpha}$. Then,

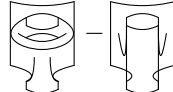

$$(\sigma d)_{\alpha,\beta}^i \Sigma_{\alpha,\alpha}^i = (-1)^{r_{\sigma\alpha,\sigma\beta}} \text{sign}(\sigma_\alpha) D_{\alpha,\beta}$$

$$\Sigma_{\beta,\beta}^{i+1} d_{\alpha,\beta}^i = \text{sign}(\sigma_\beta) (-1)^{r_{\alpha,\beta}} D_{\alpha,\beta}$$

The permutation on $R_\beta = R_\alpha \sqcup \{k\}$ can be gotten as the permutation on R_α followed by moving k . Thus, if $\text{sign}(\sigma_\alpha) = \text{sign}(\sigma_\beta)$, then σ moves k an even number of places in the ordering of R_β . But $r_{\alpha,\beta}$ is the number of elements j of $R_{\alpha,\beta}$ with $j < k$. So, $r_{\alpha,\beta} = r_{\sigma\alpha,\sigma\beta} \pmod 2$. Alternatively, if $\text{sign}(\sigma_\alpha) \neq \text{sign}(\sigma_\beta)$, then σ moves k an odd number of places and $r_{\alpha,\beta} \neq r_{\sigma\alpha,\sigma\beta} \pmod 2$. Thus, $(\sigma d)^i \Sigma^i = \Sigma^{i+1} d^i$ so Σ is a chain map. Indeed, Σ is invertible since σ is. Thus, $[D_K]$ and $[\sigma D_K]$ are isomorphic. This works in the graded case too since shifts have no effect.

Positive Writhe Reidemeister 1. Define chain maps:

$$\begin{array}{ccccccc} \left[\begin{array}{c} \text{Y} \\ \text{Y} \end{array} \right] \{-\frac{3}{2}\} & 0 \leftarrow & \text{Y}\{-2\} & \leftarrow & \text{Y}\{-1\} & \leftarrow & 0 \\ \uparrow & = & \uparrow & & \uparrow & & \\ \left[\text{Y} \right] & 0 \leftarrow & 0 & \leftarrow & \text{Y} & \leftarrow & 0 \end{array}$$

where \uparrow is the difference of degree -1 cobordisms  and

$$\begin{array}{ccccccc} \left[\text{Y} \right] & 0 \leftarrow & 0 & \leftarrow & \text{Y} & \leftarrow & 0 \\ \uparrow & = & \uparrow & & \uparrow & & \\ \left[\text{Y} \right] \{-\frac{3}{2}\} & 0 \leftarrow & \text{Y}\{-2\} & \leftarrow & \text{Y}\{-1\} & \leftarrow & 0 \end{array}$$

where \uparrow is the degree 1 cobordism .

We can see that these are chain maps. The only thing to check is that

$$\text{[Diagram 1]} - \text{[Diagram 2]} = 0$$

since the cobordisms are isotopic. We can also see that the composition $\begin{matrix} [\mathcal{U}] \\ \uparrow \\ [\mathcal{S}] \{-\frac{3}{2}\} \\ \uparrow \\ [\mathcal{U}] \end{matrix}$ is the identity since

$$\text{[Diagram 3]} - \text{[Diagram 4]} = \text{[Diagram 5]}$$

by the torus relation. We can construct a homotopy between the composition

$$\begin{matrix} [\mathcal{S}] \{-\frac{3}{2}\} \\ \uparrow \\ [\mathcal{U}] \\ \uparrow \\ [\mathcal{S}] \{-\frac{3}{2}\} \end{matrix}$$

and the identity:

$$\begin{array}{ccccccc} 0 & \leftarrow & \mathcal{U}\{-2\} & \leftarrow & \mathcal{S}\{-1\} & \leftarrow & 0 \\ & \nearrow & & \nearrow & & \nearrow & \\ 0 & \leftarrow & \mathcal{U}\{-2\} & \leftarrow & \mathcal{S}\{-1\} & \leftarrow & 0 \end{array}$$

where $\begin{matrix} \mathcal{O} \\ \uparrow \\ \mathcal{U} \end{matrix}$ is the degree 1 cobordism [Diagram 6] . To see it is a homotopy we need to

check two things.

$$\begin{array}{l} \text{[Diagram 7]} = \text{[Diagram 8]} \\ \text{[Diagram 9]} = \text{[Diagram 10]} - \text{[Diagram 11]} + \text{[Diagram 12]} \end{array}$$

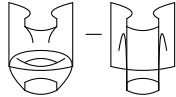

The first is trivial and the second follows from the four tube relation. Thus, $[\mathcal{S}] \{-1\}$ and $[\mathcal{U}]$ are homotopy equivalent.

Negative Writhe Reidemeister 1. Define chain maps:

$$\begin{array}{ccccccc} [\mathcal{C}]\{\frac{3}{2}\} & 0 & \leftarrow & \mathcal{O}\{1\} & \leftarrow & \mathcal{U}\{2\} & \leftarrow & 0 \\ \uparrow & = & & \uparrow & & \uparrow & & \\ [\mathcal{U}] & 0 & \leftarrow & \mathcal{U} & \leftarrow & 0 & \leftarrow & 0 \end{array}$$

where $\begin{array}{c} \mathcal{O} \\ \uparrow \\ \mathcal{U} \end{array}$ is the degree 1 cobordisms  and

$$\begin{array}{ccccccc} [\mathcal{U}] & 0 & \leftarrow & \mathcal{U} & \leftarrow & 0 & \leftarrow & 0 \\ \uparrow & = & & \uparrow & & \uparrow & & \\ [\mathcal{C}]\{\frac{3}{2}\} & 0 & \leftarrow & \mathcal{O}\{1\} & \leftarrow & \mathcal{U}\{2\} & \leftarrow & 0 \end{array}$$

where $\begin{array}{c} \mathcal{U} \\ \uparrow \\ \mathcal{O} \end{array}$ is the difference of degree -1 cobordisms . Once again,

these are chain maps and the composition $\begin{array}{c} [\mathcal{U}] \\ \uparrow \\ [\mathcal{C}]\{\frac{3}{2}\} \\ \uparrow \\ [\mathcal{U}] \end{array}$ is the identity by the torus

relation. Also, by the four tube relation, the composition $\begin{array}{c} [\mathcal{C}]\{\frac{3}{2}\} \\ \uparrow \\ [\mathcal{U}] \\ \uparrow \\ [\mathcal{C}]\{\frac{3}{2}\} \end{array}$ is homotopic to the identity by

$$\begin{array}{ccccccc} 0 & \leftarrow & \mathcal{O}\{1\} & \leftarrow & \mathcal{U}\{2\} & \leftarrow & 0 \\ & \nearrow & & \nearrow & & \nearrow & \\ 0 & \leftarrow & \mathcal{O}\{1\} & \leftarrow & \mathcal{U}\{2\} & \leftarrow & 0 \end{array}$$

where $\begin{array}{c} \mathcal{U} \\ \uparrow \\ \mathcal{O} \end{array}$ is the degree 1 cobordism . Thus $[\mathcal{C}]\{\frac{3}{2}\}$ and $[\mathcal{U}]$ are homotopy equivalent.

Reidemeister 2. We can also construct chain maps

$$\begin{array}{ccccccc} [\mathcal{C}] & 0 & \leftarrow & \mathcal{U}\{-1\} & \leftarrow & \mathcal{U}\{\oplus\mathcal{O}\} & \leftarrow & \mathcal{U}\{1\} & \leftarrow & 0 \\ \uparrow & = & & \uparrow & & \uparrow & & \uparrow & & \\ [\mathcal{C}] & 0 & \leftarrow & 0 & \leftarrow & \mathcal{U}\{\} & \leftarrow & 0 & \leftarrow & 0 \end{array}$$

where $\begin{matrix} \{\!\!\} \oplus \{\!\!\} \\ \uparrow \\ \{\!\!\} \end{matrix}$ is the matrix of degree 0 cobordisms $\left(\begin{matrix} \text{[Diagram 1]} \\ \text{[Diagram 2]} \end{matrix} \right)$ and

$$\begin{matrix} [\{\!\!\}] \\ \uparrow \\ [\{\!\!\}] \end{matrix} = \begin{matrix} 0 \leftarrow 0 \leftarrow \{\!\!\} \leftarrow 0 \leftarrow 0 \\ 0 \leftarrow \{\!\!\{-1\} \leftarrow \{\!\!\} \oplus \{\!\!\} \leftarrow \{\!\!\{1\} \leftarrow 0 \end{matrix}$$

where $\begin{matrix} \{\!\!\} \\ \uparrow \\ \{\!\!\} \oplus \{\!\!\} \end{matrix}$ is the matrix of signed degree 0 cobordisms $\left(\begin{matrix} \text{[Diagram 3]} & - \text{[Diagram 4]} \end{matrix} \right)$.

These are chain maps since

$$\text{[Diagram 5]} - \text{[Diagram 6]} = 0$$

$$\text{[Diagram 7]} - \text{[Diagram 8]} = 0$$

The composition $\begin{matrix} [\{\!\!\}] \\ \uparrow \\ [\{\!\!\}] \\ \uparrow \\ [\{\!\!\}] \end{matrix}$ is the identity since by the sphere relation

$$\text{[Diagram 9]} - \text{[Diagram 10]} = \text{[Diagram 11]}$$

There is a homotopy between $\begin{matrix} [\{\!\!\}] \\ \uparrow \\ [\{\!\!\}] \\ \uparrow \\ [\{\!\!\}] \end{matrix}$ and the identity given by

$$\begin{matrix} 0 \leftarrow \{\!\!\{-1\} \leftarrow \{\!\!\} \oplus \{\!\!\} \leftarrow \{\!\!\{1\} \leftarrow 0 \\ \nearrow \quad \nearrow \quad \nearrow \quad \nearrow \\ 0 \leftarrow \{\!\!\{-1\} \leftarrow \{\!\!\} \oplus \{\!\!\} \leftarrow \{\!\!\{1\} \leftarrow 0 \end{matrix}$$

where $\begin{matrix} \uparrow \\ \text{---} \\ \text{---} \oplus \text{---} \\ \text{---} \end{matrix}$ and $\begin{matrix} \text{---} \oplus \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ are degree 1 matrices $\begin{pmatrix} 0 & \text{---} \\ & \text{---} \end{pmatrix}$ and $\begin{pmatrix} 0 \\ - & \text{---} \end{pmatrix}$.

This is a homotopy since $\begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} = \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix}$, $\begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} = \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix}$, and

$$\begin{pmatrix} 0 & \text{---} \\ & \text{---} \\ 0 & \text{---} \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ \text{---} & \text{---} \\ 0 & \text{---} \end{pmatrix} = \begin{pmatrix} \text{---} & 0 \\ & \text{---} \\ 0 & \text{---} \end{pmatrix} - \begin{pmatrix} \text{---} & \text{---} \\ \text{---} & \text{---} \\ \text{---} & \text{---} \end{pmatrix}$$

The only nontrivial part is the bottom right entry of the matrix equation which follows from the four tube relation.

Reidemeister 3. By the skein relation we have that $\begin{matrix} \text{---} \\ \text{---} \end{matrix}$ and $\begin{matrix} \text{---} \\ \text{---} \end{matrix}$ are cones

of the chain maps $\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ and $\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ induced by $\begin{matrix} \text{---} \\ \text{---} \end{matrix}$. The Reidemeister 2

homotopy equivalence is a strong deformation retract: $\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ is the identity and

$\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ is homotopic to the identity. Thus, by the properties of cones, $\begin{matrix} \text{---} \\ \text{---} \end{matrix}$ and

$\begin{matrix} \text{---} \\ \text{---} \end{matrix}$ are homotopy equivalent to the cones of $\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ and $\begin{matrix} \text{---} \\ \uparrow \\ \text{---} \end{matrix}$ which are equal

as chain maps.

Invariance Proof. Since permutations induce isomorphisms, the isomorphism class of Khovanov brackets is independent of ordering. Two blackboard diagrams for a tangle K are related locally by Reidemeister moves. Reidemeister 2 and 3

moves induce local isomorphisms. Framed Reidemeister 1 moves, that is elimination of adjacent positive and negative writhe twists, induce a local isomorphism of the Khovanov bracket: that isomorphism is the horizontal composite of the 2 Reidemeister 1 isomorphisms obtained above. Thus, by locality, the theorem follows.
